Would you roll back R17?

Open the definition you approved with Sai. Engineering wants your first call in writing. Keep it so you can show exactly which evidence changes your mind.

The five-minute catch-and-fix audit

SEVEN MISTAKES, SEVEN CHECKS, SEVEN FIXES

Mistake	Check	Fix
Analysis without an action	Finish “If X, we will Y”	Write the decision brief
Unclear metric	Expose the definition and inferred fields	Write a metric contract
Wrong unit	Compare COUNT(*) with COUNT(DISTINCT) and check duplicates at the intended grain	Count at the intended grain
Mismatched periods	Check maturity and completeness	Rerun like for like
Plausible table without lineage	Check use, freshness and a tie-out against a trusted source	Tie out before you rely on it
Pattern becomes a cause	Write down the evidence that would disprove it	Keep the disproof beside the claim
Polished answer with a trust gap	Name the first failed check	Choose a response and record when to reopen; for a polished self-audit, open the execution evidence

PRIORITY

- For a short audit, run the like-for-like and grain checks first.
- Skipping the causal check is costly: a pattern is not a cause until disproof is written down.

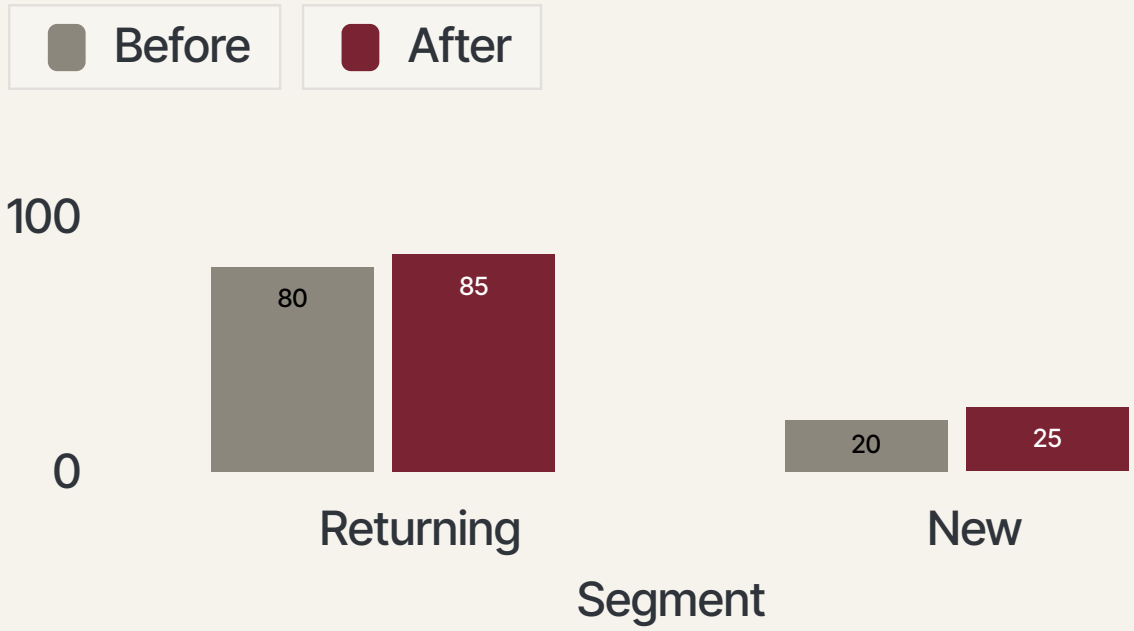

Source: Catch 7 AI Analysis Mistakes Before They Drive Decisions, Paras Doshi, slide 14

Read the counts before the headline.

Returning accounts: 640 of 800 activated before the release and 170 of 200 after.

New accounts: 40 of 200 before and 200 of 800 after.

Sketch what changed inside each group.

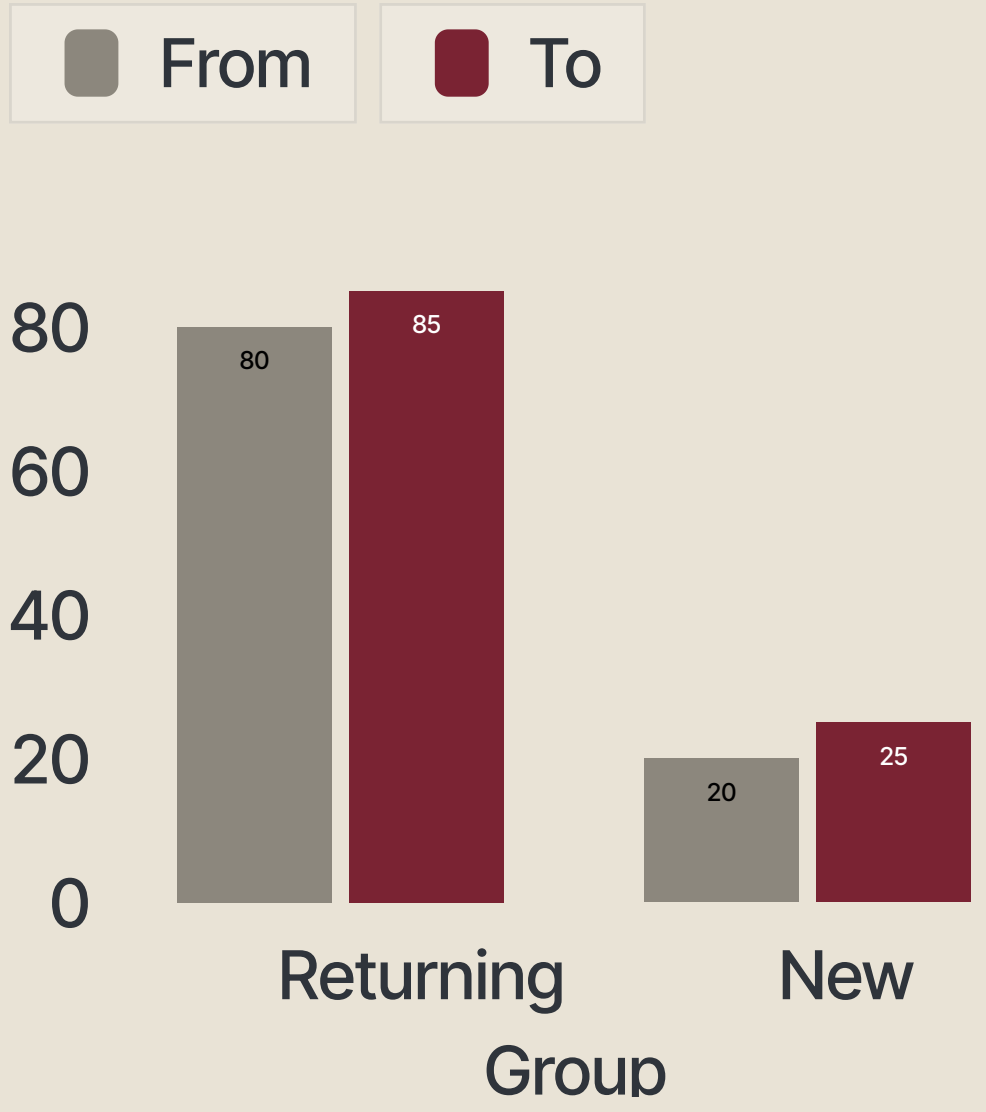

SEGMENT	BEFORE	AFTER	RATE CHANGE
Returning	640/800 = 80%	170/200 = 85%	80% → 85%
New	40/200 = 20%	200/800 = 25%	20% → 25%
Overall	**680/1000 = 68%**	**370/1000 = 37%**	**68% → 37%**

How can both groups improve while the total falls?

The returning group went from 80% to 85%.
The new group went from 20% to 25%.

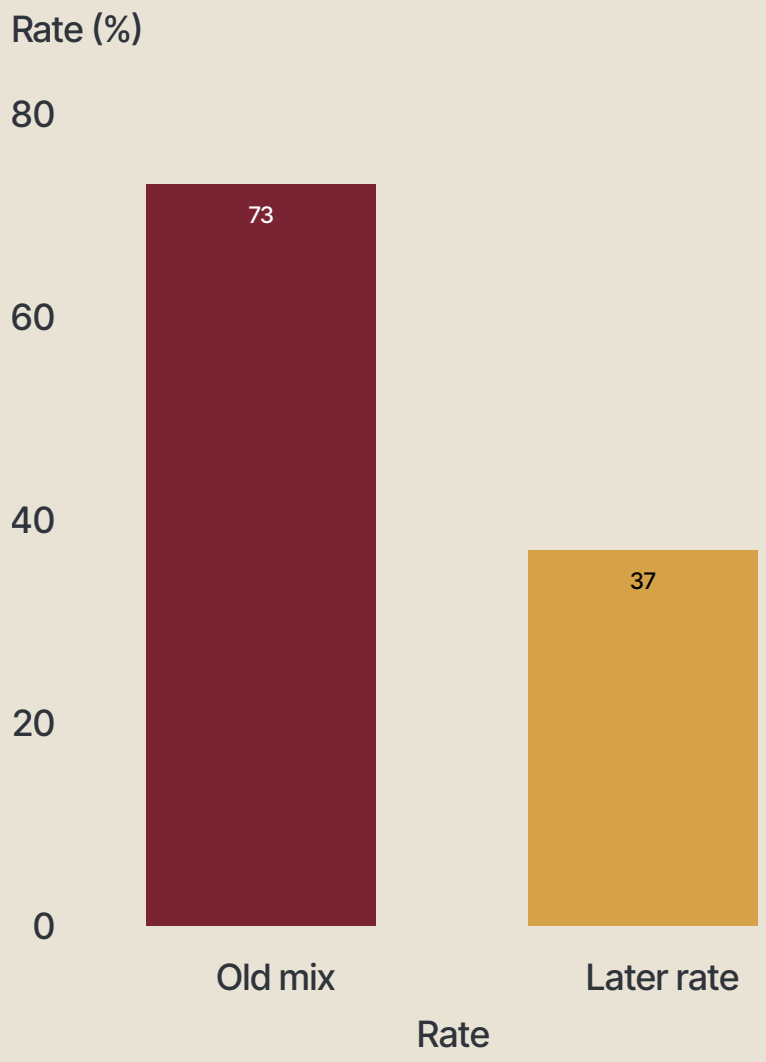

Now look at the bottom of each fraction. **Who makes up most of the later population?**

Keep the old population mix for one calculation.

$0.8 \times 85\% + 0.2 \times 25\% = 73\%$

At the old mix, the later rate would be 73%. At the actual later mix it was 37%. That 36-point gap comes from changing the weights. It tells engineering nothing about what a rollback would do.

Find the sentence an engineer could act on.

A recorded baseline answer said a rollback **“would sacrifice a likely small gain.”**

The arithmetic was right.

Ask your partner which observation establishes that the release produced the gain.

Give engineering an answer it can use.

The engineering lead needs a recommendation. Keep R17 running while engineering checks exposure. If comparable exposed accounts did worse than unexposed accounts, reopen the rollback decision. Send the counts and name the comparison you need.

What does the shift log let Engineering do?

First save your call from the activation counts. Now open the engineer's shift log and compare the two randomized groups with the agreed timeout threshold. What should the engineer do with the flag? What can Growth still say about activation?
