Who would you trust with your Monday report?

Think of an AI agent as a new grad with infinite energy who wants to please you. You still have to teach it the business, show it when to push back and check whether two people get the same answer.

Did the store keep its promise?

The store promised a complete desk by Friday. It ships in three boxes. Two arrive Friday. The box with the legs arrives Monday.

Carrier: 2 of **3 boxes** arrived on time (67%).

Store: 0 of **1 complete orders** arrived on time (0%).

To decide whether to credit the customer for a missed delivery promise, count complete orders.

Teach it to challenge you

Try asking, “Why did our release improve activation?” Now ask, “What would we need to see to say the release helped?” Which question gives the analyst room to disagree?

Give two analysts the same job

Start two clean chats. Ask for the active rate. Before you compare their numbers, compare who each counted and over what period. Agreeing on a number is useful only if the definition is right.

Chat	Active rate
Chat A	68%
Chat B	50%
Chat C	68%

Write down what ‘activated’ means

Count eligible accounts that activated at least once within seven days. One account can retry an import several times. Decide which of those events belong in the numerator.

Build your first semantic model

Open starter/model.json. Name the source, describe what one row represents, write the calculation and identify the person who can approve a change. Save your reviewed copy in work/model.json.

Try to break your definition

What should the report show when zero accounts were eligible? Run python3 verify.py model. Open the SQL it checked and explain the empty result to someone who has never read SQL.
