“Are you telling me to roll this back?”

Sai has the first answer on screen. Paras is playing the engineering lead.

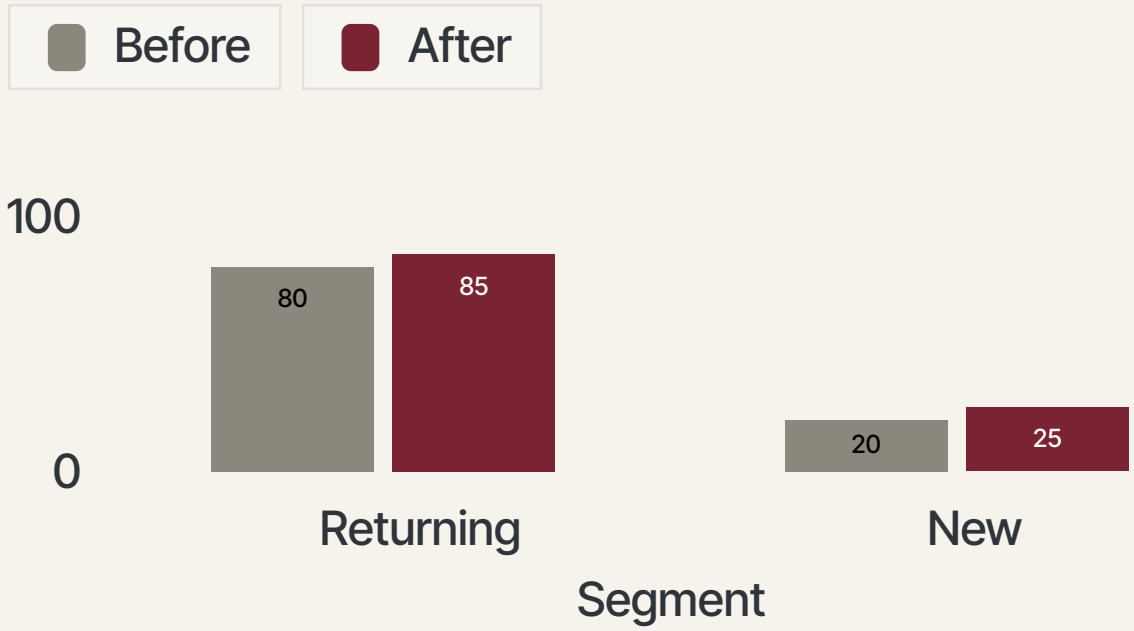

Before doing any more analysis, write down exactly what you would say to him.

Read the counts before the headline.

Returning accounts: 640 of 800 activated before the release and 170 of 200 after.

New accounts: 40 of 200 before and 200 of 800 after.

Sketch what changed inside each group.

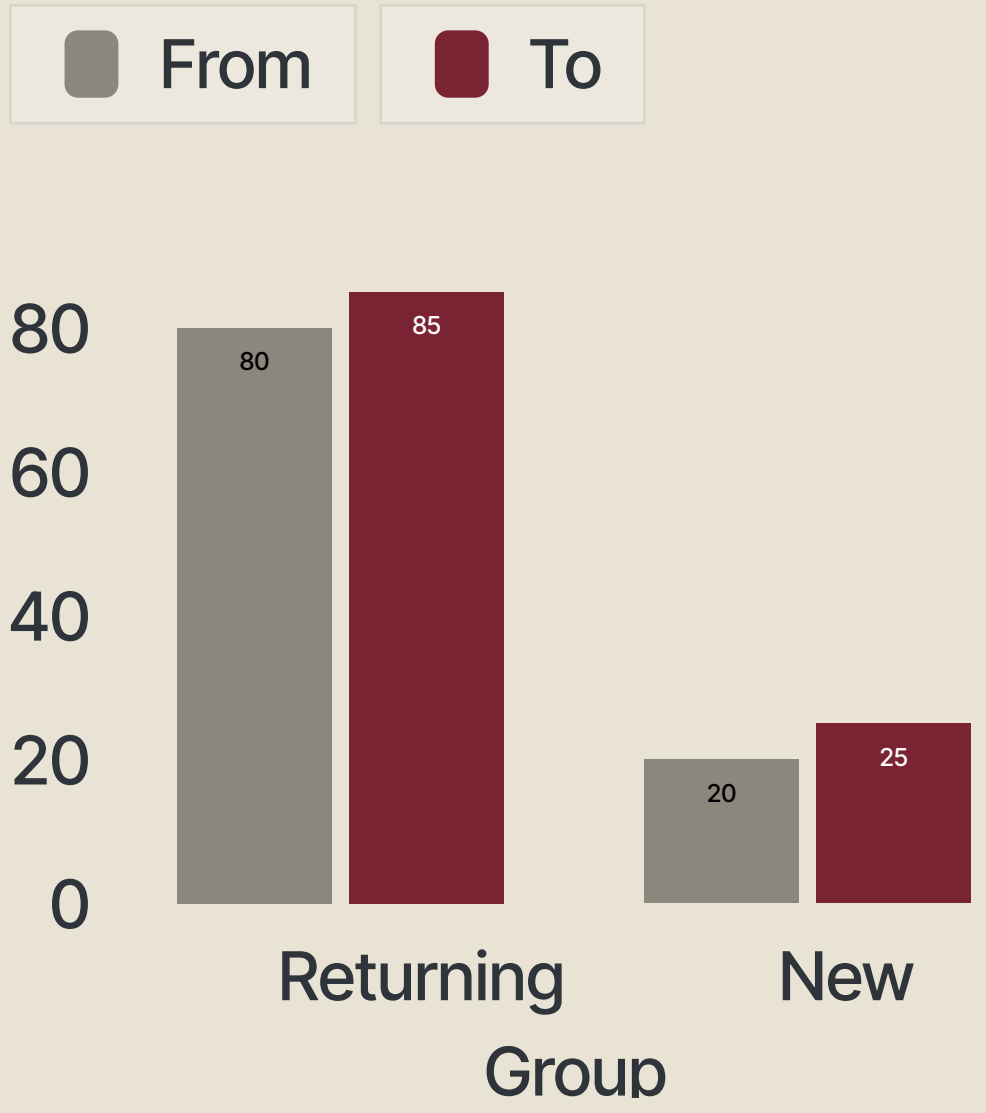

SEGMENT	BEFORE	AFTER	RATE CHANGE
Returning	640/800 = 80%	170/200 = 85%	80% → 85%
New	40/200 = 20%	200/800 = 25%	20% → 25%
Overall	**680/1000 = 68%**	**370/1000 = 37%**	**68% → 37%**

How can both groups improve while the total falls?

The returning group went from 80% to 85%.
The new group went from 20% to 25%.

Now look at the bottom of each fraction. **Who makes up most of the later population?**

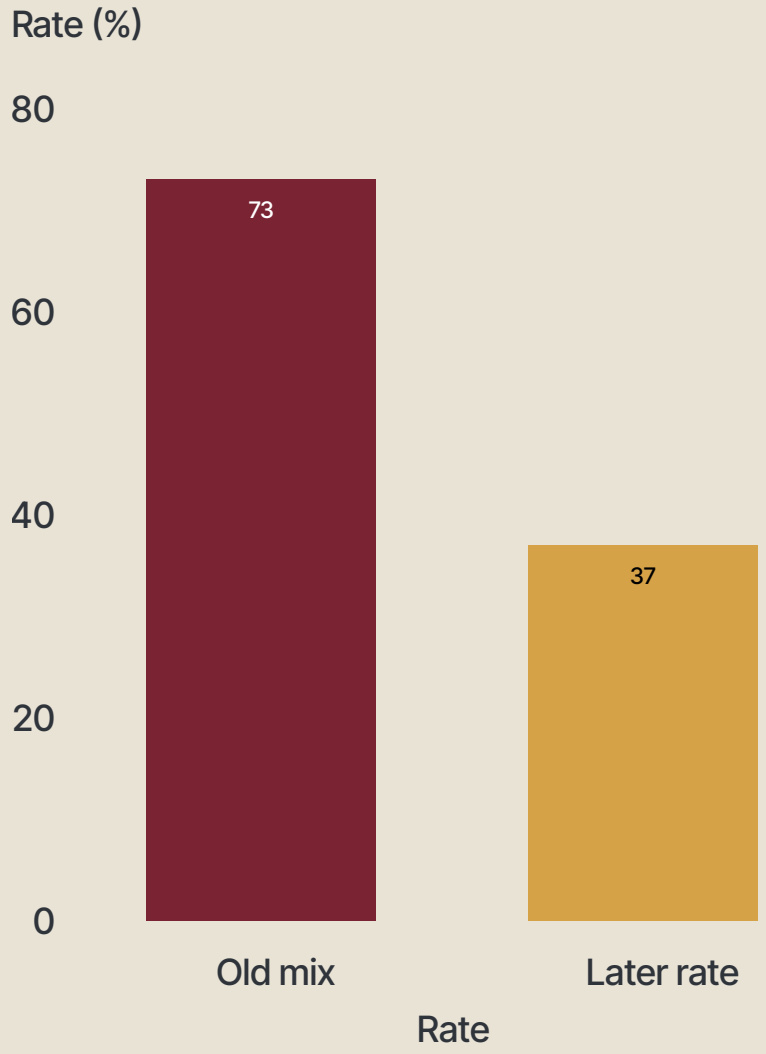

Keep the old population mix for one calculation.

Apply the later rates to the old mix:

$$0.8 \times 85\% + 0.2 \times 25\% = 73\%$$

The actual later rate was 37%.

That gap tells you how much the population changed.

Find the sentence an engineer could act on.

A recorded baseline answer said a rollback **“would sacrifice a likely small gain.”**

The arithmetic was right.

Ask your partner which observation establishes that the release produced the gain.

Give engineering an answer it can use.

State what changed.

Say what remains uncertain.

Ask for release exposure and a credible comparison.

Keep both your first answer and the sentence you're willing to sign.
