Would you roll it back?

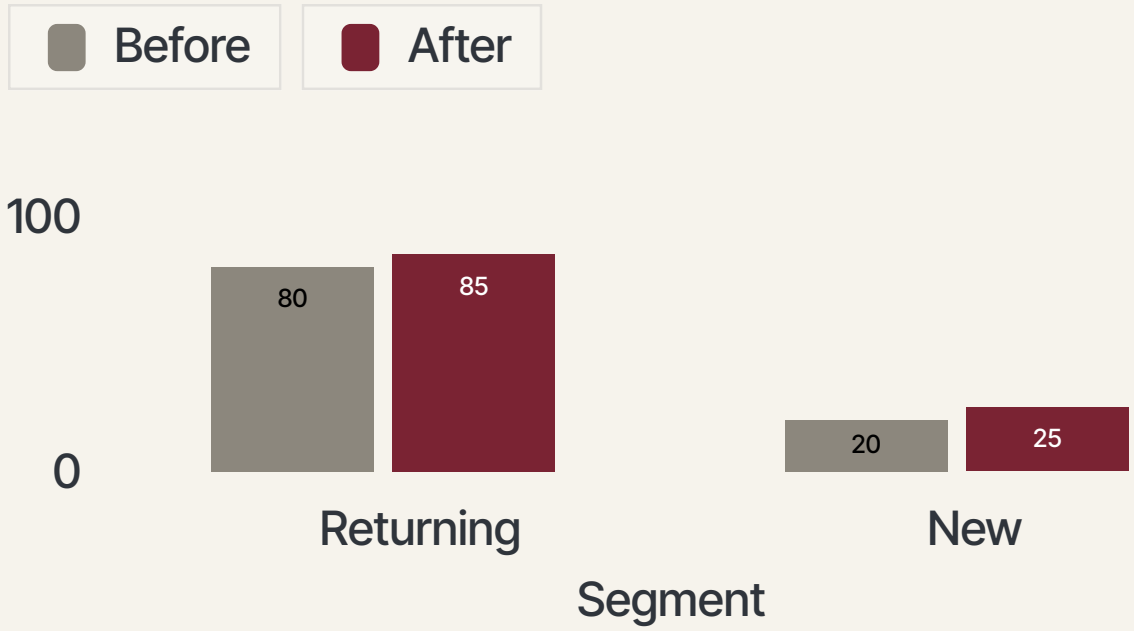

The engineering lead is waiting. Write the sentence you'd send now. What would change your mind?

Read the counts before the headline.

Returning accounts: 640 of 800 activated before the release and 170 of 200 after.

New accounts: 40 of 200 before and 200 of 800 after.

Sketch what changed inside each group.

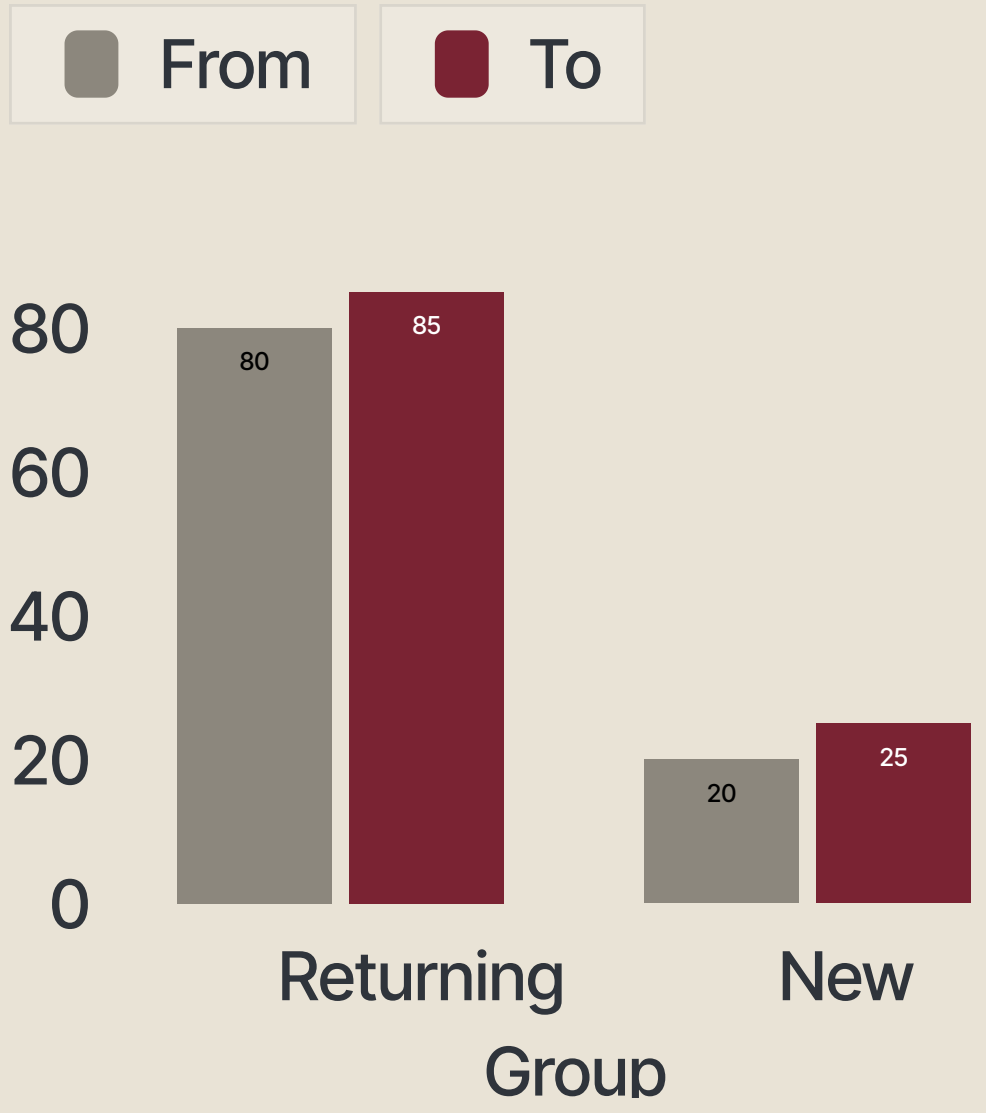

SEGMENT	BEFORE	AFTER	RATE CHANGE
Returning	640/800 = 80%	170/200 = 85%	80% → 85%
New	40/200 = 20%	200/800 = 25%	20% → 25%
Overall	**680/1000 = 68%**	**370/1000 = 37%**	**68% → 37%**

How can both groups improve while the total falls?

The returning group went from 80% to 85%.
The new group went from 20% to 25%.

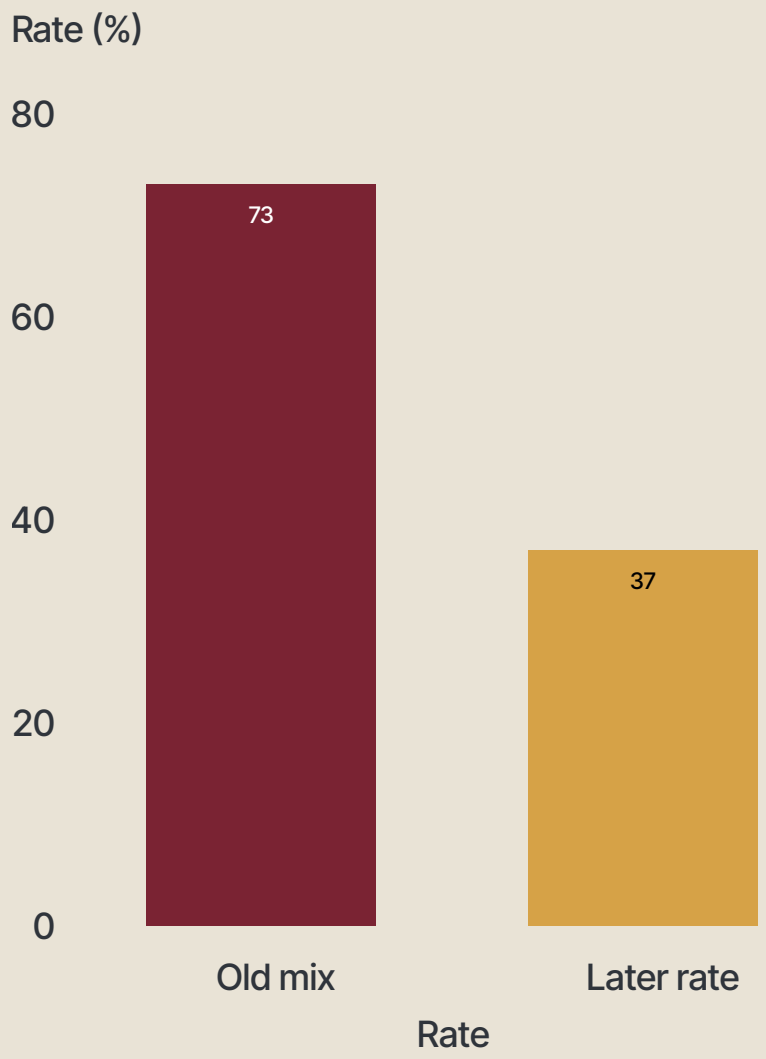

Now look at the bottom of each fraction. **Who makes up most of the later population?**

Keep the old population mix for one calculation.

$0.8 \times 85\% + 0.2 \times 25\% = 73\%$

At the old mix, the later rate would be 73%. At the actual later mix it was 37%. That 36-point gap comes from changing the weights. It tells engineering nothing about what a rollback would do.

Find the sentence an engineer could act on.

A recorded baseline answer said a rollback **“would sacrifice a likely small gain.”**

The arithmetic was right.

Ask your partner which observation establishes that the release produced the gain.

Give engineering an answer it can use.

The engineering lead needs a recommendation. Keep R17 running while engineering checks exposure. If comparable exposed accounts did worse than unexposed accounts, reopen the rollback decision. Send the counts and name the comparison you need.
